(57) **ABSTRACT**

A horizontal multi-joint robot includes: a first joint capable of swiveling around a first axis; a second joint capable of swiveling around a second axis that is parallel to and spaced apart from the first axis; and a duct connected between the first joint and the second joint. The first joint has a first connecting portion forming a predetermined angle relative to the first axis. The second joint has a second connecting portion forming a predetermined angle relative to the second axis. The duct has a first end and a second end. The first end is connected to the first connecting portion. The second end is connected to the second connecting portion.

FIG. 4

FIG. 5

1

HORIZONTAL MULTI-JOINT ROBOT AND ROBOT

BACKGROUND

1. Technical Field

The present invention relates to a horizontal multi-joint robot and a robot.

2. Related Art

JP-A-2009-226567 describes a horizontal multi-joint robot (SCARA robot) according to the related art. The horizontal multi-joint robot described in JP-A-2009-226567 has a pedestal, a first arm mounted on the pedestal so that the first arm can swivel (i.e., turn, rotate or pivot), a second arm mounted on the first arm so that the second arm can swivel, a work head mounted on the second arm, and a harness (duct) with one side thereof mounted on the pedestal and the other side thereof mounted on the second arm. Wires and pipes connected to a second arm drive motor and a work head drive motor are housed inside the harness. Such a horizontal multi-joint robot of JP-A-2009-226567 has, for example, the following two problems.

The first problem is that driving of the horizontal multi-joint robot causes the harness to shake and thus generates unwanted vibration. Specifically, in the horizontal multi-joint robot of JP-A-2009-226567, the root of the harness on the pedestal side is shifted from the axis of the first arm and the root of the harness on the second arm side is shifted from the axis of the second arm. Therefore, when the first and second arms swivel, the distance between both roots of the harness changes and this change causes the harness to deform and vibrate unnecessarily. Also, the swiveling of the first and second arms causes the harness to twist and vibrate unnecessarily. Such unnecessary vibration of the harness causes deterioration in the vibration damping of the horizontal multi-joint robot (increases the time required for the vibration to subside to a predetermined magnitude).

The second problem is that the horizontal multi-joint robot is increased in size. Specifically, the harness has a large height since both ends of the harness extend directly upward so as to coincide with the axes of the first and second arms. Therefore, a large space is required to place the harness which increases the size of the horizontal multi-joint robot.

SUMMARY

An advantage of some aspects of the invention is that a horizontal multi-joint robot and a robot in which vibration of the duct at the time of driving can be restrained and the installation space of the duct can be reduced.

An aspect of the disclosure is directed to a horizontal multi-joint robot including: a first joint capable of swiveling around a first axis; a second joint capable of swiveling around a second axis that is parallel to the first axis and spaced apart from the first axis; and a duct connected to the first joint and the second joint. The first joint is provided with a first connecting portion forming a predetermined angle relative to the first axis. The second joint is provided with a second connecting portion forming a predetermined angle relative to the second axis. The duct has a first end and a second end. The first end is connected to the first connecting portion. The second end is connected to the second connecting portion.

With this configuration, a horizontal multi-joint robot is provided in which vibration of the duct at the time of driving can be restrained and the installation space of the duct can be reduced.

2

In the horizontal multi-joint robot of the aspect of the disclosure, it is preferable that the first connecting portion is inclined toward the second axis and that the second connecting portion is inclined toward the first axis.

With this configuration, the total length of the duct can be reduced and the curvature of the duct can be restrained to a small value. Therefore, vibration of the duct at the time when the first and second arms are driven or when the driving is stopped can be prevented or restrained.

In the horizontal multi-joint robot of the aspect of the disclosure, it is preferable that a duct connecting portion of the first joint and a duct connecting portion of the second joint are provided within the same plane as the normals of the first axis and the second axis.

With this configuration, the curvature of the duct can be made substantially constant along the axial direction. That is, the concentration of a bending stress on a predetermined part of the duct can be prevented or restrained.

In the horizontal multi-joint robot of the aspect of the disclosure, it is preferable that, if a center axis of the first connecting portion is a third axis, a center axis of the second connecting portion is a fourth axis, an angle formed by the third axis and the first axis is θ_1 , and an angle formed by the fourth axis and the second axis is θ_2 , a relation of $\theta_1 = \theta_2$ is satisfied.

With this configuration, the curvature of the duct can be made substantially constant along the axial direction. That is, the concentration of a bending stress on a predetermined part of the duct can be prevented or restrained.

In the horizontal multi-joint robot of the aspect of the disclosure, it is preferable that, if a center axis of the first connecting portion is a third axis, a center axis of the second connecting portion is a fourth axis, an angle formed by the third axis and the first axis is θ_1 , and an angle formed by the fourth axis and the second axis is θ_2 , each of the angles θ_1 and θ_2 is 10° or greater and 60° or smaller.

With this configuration, the maximum height of the duct can be restrained and flexure of the first and second joints can also be restrained. Therefore, the curvature of wires within the first and second joints can be reduced and a bending stress applied to the wires can be reduced.

In the horizontal multi-joint robot of the aspect of the disclosure, it is preferable that the first joint and the second joint have the same shape and size.

Thus, the device design is simplified.

In the horizontal multi-joint robot of the aspect of the disclosure, it is preferable that, if a center axis of the first connecting portion is a third axis, and the center axis of the second connecting portion is a fourth axis, the duct extends along a circle having both the third axis and the fourth axis as tangents.

With this configuration, since an equal bending stress is applied to substantially the entire area of the duct, local concentration of stress on a predetermined part of the duct can be securely prevented.

In the horizontal multi-joint robot of the aspect of the disclosure, it is preferable that, if a distance between the first axis and the second axis is L , an average radius of curvature R of the duct satisfies a relation of $0.6L \leq R \leq L$.

With this configuration, excessive flexure of the duct is restrained. Therefore, the bending strength required of the duct can be lowered and, for example, a reduction in the weight of the duct due to a reduced thickness or the like can be realized.

3

In the horizontal multi-joint robot of the aspect of the disclosure, it is preferable that, if a distance between the first axis and the second axis is L, a relation of $100\text{ mm} \leq L \leq 2000\text{ mm}$ is satisfied.

With this configuration, the total length of the duct can be restrained and the curvature of the duct can also be reduced. Moreover, the duct can be effectively reduced in weight.

Another aspect of the disclosure is directed to a robot including: a pedestal; a first arm connected to the pedestal and capable of swiveling around a first axis in relation to the pedestal; a second arm connected to the first arm and capable of swiveling around a second axis that is parallel to the first axis and spaced apart from the first axis, in relation to the first arm; and a wiring section which accommodates a wire therein and conveys the wire from the second arm to the pedestal. The wiring section includes: a duct supporting portion provided to protrude from the pedestal and intersect with the first axis; a first joint connected to the duct supporting portion and capable of swiveling around the first axis in relation to the duct supporting portion; a second joint connected to the second arm and capable of swiveling around the second axis in relation to the second arm; and a duct connected to the first joint and the second joint. The first joint is provided with a first connecting portion forming a predetermined angle relative to the first axis. The second joint is provided with a second connecting portion forming a predetermined angle relative to the second axis. The duct has a first end and a second end. The first end is connected to the first connecting portion. The second end is connected to the second connecting portion.

With this configuration, a robot is provided in which vibration of the duct at the time of driving can be restrained and the installation space of the duct can be reduced.

BRIEF DESCRIPTION OF THE DRAWINGS

Embodiments of the invention will be described with reference to the accompanying drawings, wherein like numbers reference like elements.

FIG. 1 is a view showing a preferred embodiment of a horizontal multi-joint robot.

FIG. 2 is an enlarged sectional view of a wiring section provided in the horizontal multi-joint robot shown in FIG. 1.

FIG. 3 is a perspective view showing a preferred embodiment of a robot.

FIG. 4 is a view showing a first wiring section provided in the robot shown in FIG. 3.

FIG. 5 is a view showing a second wiring section provided in the robot shown in FIG. 3.

DESCRIPTION OF EXEMPLARY EMBODIMENTS

Hereinafter, a preferred embodiment of a horizontal multi-joint robot and a robot will be described in detail with reference to the drawings.

Horizontal Multi-Joint Robot

First, a horizontal multi-joint robot will be described.

FIG. 1 is a view showing a preferred embodiment of a horizontal multi-joint robot. FIG. 2 is an enlarged sectional view of a wiring section provided in the horizontal multi-joint robot shown in FIG. 1.

As shown in FIG. 1, a horizontal multi-joint robot (SCARA robot: horizontal multi-joint robot) 100 has a pedestal 110, a first arm 120, a second arm 130, a work head 140, an end effector 150, and a wiring section 160. The horizontal multi-

4

joint robot 100 is a representative example of a horizontal multi-joint robot and also a robot.

The pedestal 110 is fixed, for example, to a floor surface, not shown, with bolts or the like. The first arm 120 is connected to an upper end of the pedestal 110. The first arm 120 is capable of swiveling around a first axis J1 that extends along a vertical direction, in relation to the pedestal 110.

Inside the pedestal 110, a first motor 111 which causes the first arm 120 to swivel, and a first decelerator 112 are installed. An input axis of the first decelerator 112 is connected to a rotation axis of the first motor 111. An output axis of the first decelerator 112 is connected to the first arm 120. Therefore, when the first motor 111 is driven and a driving force thereof is transmitted to the first arm 120 via the first decelerator 112, the first arm 120 swivels within a horizontal plane around the first axis J1 in relation to the pedestal 110. The first motor 111 is provided with a first encoder 113 which outputs a pulse signal corresponding to the amount of rotation of the first motor 111. Based on the pulse signal from the first encoder 113, driving (amount of swiveling) of the first arm 120 in relation to the pedestal 110 can be detected.

The second arm 130 is connected to a distal end of the first arm 120. The second arm 130 is capable of swiveling around a second axis J2 that extends along a vertical direction, in relation to the first arm 120.

Inside the second arm 130, a second motor 131 which causes the second arm 130 to swivel, and a second decelerator 132 are installed. An input axis of the second decelerator 132 is connected to a rotation axis of the second motor 131. An output axis of the second decelerator 132 is connected and fixed to the first arm 120. Therefore, when the second motor 131 is driven the a driving force thereof is transmitted to the first arm 120 via the second decelerator 132, the second arm 130 swivels within a horizontal plane around the second axis J2 in relation to the first arm 120. The second motor 131 is provided with a second encoder 133 which outputs a pulse signal corresponding to the amount of rotation of the second motor 131. Based on the pulse signal from the second encoder 133, driving (amount of swiveling) of the second arm 130 in relation to the first arm 120 can be detected.

The work head 140 is arranged at a distal end of the second arm 130. The work head 140 has a spline nut 141 and a ball screw nut 142 that are coaxially arranged at the distal end of the second arm 130, and a spline shaft 143 inserted in the spline nut 141 and the ball screw nut 142. The spline shaft 143 is rotatable around its axis in relation to the second arm 130 and also capable of moving up and down (ascent and descent).

Inside the second arm 130, a rotation motor 144 and a lift motor 145 are arranged. A driving force of the rotation motor 144 is transmitted to the spline nut 141 by a driving force transmission mechanism, not shown. As the spline nut 141 rotates forward and backward, the spline shaft 143 rotates forward and backward around an axis J5 that extends along a vertical direction. The rotation motor 144 is provided with a third encoder 146 which outputs a pulse signal corresponding to the amount of rotation of the rotation motor 144. Based on the pulse signal from the third encoder 146, the amount of rotation of the spline shaft 143 in relation to the second arm 130 can be detected.

A driving force of the lift motor 145 is transmitted to the ball screw nut 142 by a driving force transmission mechanism, not shown. As the ball screw nut 142 rotates forward and backward, the spline shaft 143 moves up and down. The lift motor 145 is provided with a fourth encoder 147 which outputs a pulse signal corresponding to the amount of rotation of the lift motor 145. Based on the pulse signal from the fourth

5

encoder **147**, the amount of movement of the spline shaft **143** in relation to the second arm **130** can be detected.

The end effector **150** is connected to a distal end (lower end) of the spline shaft **143**. The end effector **150** is not particularly limited and may include, for example, a unit which holds an object to be carried, a unit which processes an object to be processed, or the like.

Plural wires **170** connected to individual electronic components (for example, the second motor **131**, the rotation motor **144**, the lift motor **145**, the second, third and fourth encoders **133**, **146**, **147** and the like) arranged inside the second arm **130** pass through the pipe-like wiring section **160** connecting the second arm **130** and the pedestal **110** to each other and are drawn into the pedestal **110**. Moreover, the plural wires **170** are bundled inside the pedestal **110** and thus drawn up to a control device, not shown, which is installed outside the pedestal **110** and generally controls the horizontal multi-joint robot **100**, along with the wires connected to the first motor **111** and the first encoder **113**.

Since the wires **170** of the individual electronic components inside the second arm **130** are thus drawn into the pedestal **110** via the wiring section **160**, no space for drawing the wires **170** needs to be secured within the pedestal **110**, the first arm **120** and the second arm **130**. Also, for example, the second motor **131** and the second decelerator **132** need not be hollow in order to draw the wires **170** from the second arm **130** to the first arm **120**, and an increase in the size of the second motor **131** and the second decelerator **132** is restrained. Similarly, for example, the first motor **111** and the first decelerator **112** need not be hollow in order to draw the wires **170** from the first arm **120** to the pedestal **110**, and an increase in the size of the first motor **111** and the first decelerator **112** is restrained. Therefore, the pedestal **110**, the first arm **120**, and the second arm **130** can be reduced in size. Also, the total weight of the pedestal **110**, the first arm **120**, and the second arm **130** (the weight including each internal device) can be restrained. Therefore, a reduction in the size and weight of the horizontal multi-joint robot **100** can be realized.

As shown in FIG. 1 and FIG. 2, the wiring section **160** has a duct supporting portion **161**, a first joint **162**, a second joint **163**, and a duct **164**. These components are connected in the order of the duct supporting portion **161**, the first joint **162**, the duct **164**, and the second joint **163**, from the side of the pedestal **110**. A wire insertion hole which connects the insides of the pedestal **110** and the second arm **130** to each other is formed within the wiring section **160**. That is, the duct supporting portion **161**, the first joint **162**, the second joint **163**, and the duct **164** are all pipe-shaped and have open inner spaces thereof connected in series.

The duct supporting portion **161** protrudes from a rear part on a lateral side of the pedestal **110** and extends with a gentle curve up above the pedestal **110**. Also, the duct supporting portion **161** is arranged so that an upper edge of a distal end of the duct supporting portion **161** is substantially at the same height as an upper end of the second arm **130**. The duct supporting portion **161** is rigid and does not substantially flex or deform.

The first joint **162** is connected to and received by a bearing at the distal end of the duct supporting portion **161** and is capable of swiveling around the first axis J1 in relation to the duct supporting portion **161**. Meanwhile, the second joint **163** is connected to and received by a bearing at a proximal end and upper end of the second arm **130** and is capable of swiveling around the second axis J2 in relation to the second arm **130**.

In this manner, in the horizontal multi-joint robot **100**, the axis of the first joint **162** coincides with the axis of the first

6

arm **120**, and the axis of the second joint **163** coincides with the axis of the second arm **130**. Therefore, no matter how each of the first and second arms **120**, **130** is driven, an inter-axis distance between the axes of the first and second joints **162**, **163** is kept constant. Therefore, deformation (expansion or contraction) of the duct **164** connected to the first and second joints **162**, **163** is prevented or restrained. Consequently, vibration of the duct **164** at the time when the first and second arms **120**, **130** are driven or when the driving is stopped can be prevented or restrained, and vibration of the second arm **130** can be reduced accordingly.

The first joint **162** is bent or curved in the middle in the extending direction. Therefore, it can be said that the first joint **162** has a duct supporting portion connecting portion **162a** connected to the duct supporting portion **161**, a duct connecting portion (first connecting portion) **162b** connected to the duct **164**, and a curved portion **162c** which is situated between the duct supporting portion connecting portion **162a** and the duct connecting portion **162b** and connects these portions at a predetermined angle. The duct supporting portion connecting portion **162a** is provided along a vertical direction, and a center axis thereof coincides with the first axis J1. Meanwhile, the duct connecting portion **162b** is provided so that a portion of a center axis thereof (third axis) J3 overlapping the duct **164** is inclined toward the second joint **163** in relation to the first axis J1.

The second joint **163** has the same shape and size as the first joint **162**. That is, the second joint **163** is bent or curved in the middle in the extending direction and has an arm connecting portion **163a** connected to the second arm **130**, a duct connecting portion (second connecting portion) **163b** connected to the duct **164**, and a curved portion **163c** which is situated between the arm connecting portion **163a** and the duct connecting portion **163b** and connects these portions at a predetermined angle. The arm connecting portion **163a** is provided along a vertical direction, and a center axis thereof coincides with the second axis J2. Meanwhile, the duct connecting portion **163b** is provided so that a portion of a center axis thereof (fourth axis) J4 overlapping the duct **164** is inclined toward the first joint **162** in relation to the second axis J2.

As described above, since the second joint **163** has the same shape and size as the first joint **162**, the first and second joints **162**, **163** can be used interchangeably, making it easy to design the horizontal multi-joint robot **100**. Specifically, angles $\theta 1$, $\theta 2$, described later, can be easily made equal, and the first and second joints **162**, **163** can be arranged easily at the same height, as described below.

Also, as described above, since the duct connecting portion **162b** is inclined toward the second axis J2 and the duct connecting portion **163b** is inclined toward the first axis J1, the total length of the duct **164** can be restrained and the curvature of the duct can be restrained to a small value. Therefore, vibration of the duct **164** at the time when the first and second arms **120**, **130** are driven or when the driving is stopped can be prevented or restrained.

The duct **164** is flexible and has two ends, that is, a first end **164a** and a second end **164b**. The first end **164a** is connected to the duct connecting portion **162b** of the first joint **162**. The second end **164b** is connected to the duct connecting portion **163b** of the second joint **163**.

The duct **164** is straight in its natural state and is connected to the first and second joints **162**, **163** in a bent and deformed state. Since the duct connecting portions **162b**, **163b** of the first and second joints **162**, **163** are inclined in relation to the first and second axes J1, J2, as described above, upward protrusion of the duct **164** can be restrained (the maximum height T in FIG. 1 can be restrained to a low value). Therefore,

a small and vertically short installation space for the duct **164** suffices and the horizontal multi-joint robot **100** can be reduced in size. Also, since the upward protrusion can be restrained, the total length of the duct **164** can be restrained accordingly. Therefore, vibration of the duct **164** at the time

when the first and second arms **120**, **130** are driven or when the driving is stopped can be prevented or restrained. The maximum height **T** may be preferably as short as possible and, for example, preferably shorter than a maximum reach height at the upper end of the spline shaft **143** (the height of the upper end in the state where the spline shaft **143** is situated the uppermost position). By employing such a height, the horizontal multi-joint robot **100** can be securely reduced in size.

An average radius of curvature **R** of the center axis of the duct **164** is not particularly limited. However, it is preferable that the average radius of curvature **R** satisfies the relation of $0.6L \leq R \leq L$, where the distance between the first axis **J1** and the second axis **J2** is **L**. By employing such an average radius of curvature **R**, excessive curving of the duct **164** is restrained. Therefore, the bending strength required of the duct **164** can be lowered and, for example, a reduction in weight of the duct **164** due to reduced thickness or the like can be realized.

Also, the distance **L** between the first and second axes **J1**, **J2** is not particularly limited. However, it is preferable that the distance **L** satisfies the relation of $100 \text{ mm} \leq L \leq 2000 \text{ mm}$. By employing such a distance **L**, the total length of the duct **164** can be restrained and the curvature of the duct **164** can also be reduced. Moreover, the duct **164** can be effectively reduced in weight, and vibration of the duct **164** at the time when the first and second arms **120**, **130** are driven or when the driving is stopped can be prevented or restrained more effectively.

Here, it is preferable that an angle $\theta 1$ formed by the center axis (third axis) **J3** of the duct connecting portion **162b** and the first axis **J1**, and an angle $\theta 2 (= \theta 1)$ formed by the center axis (fourth axis) **J4** of the duct connecting portion **163b** and the second axis **J2** satisfies the relation of $10^\circ \leq \theta 1, \theta 2 \leq 60^\circ$, more preferably $20^\circ \leq \theta 1, \theta 2 \leq 40^\circ$. By employing such a range of $\theta 1, \theta 2$, the maximum height **T** of the duct **164** can be restrained and excessive curving of the first and second joints **162**, **163** can be restrained. Therefore, the curvature of the wires **170** in the curved portions **162c**, **163c** of the first and second joints **162**, **163** can be reduced and bending stress applied to the wires **170** can be reduced. Also, since the applied bending stress is reduced, the strength required of the wires **170** is lowered accordingly. Thus, a reduction in diameter of the wires **170** and a reduction in weight due to the reduction in diameter can be realized.

Moreover, since the curvature of the duct **164** can be reduced, the bending stress applied to the duct **164** can be reduced. Also, since the applied bending stress is reduced, the strength required of the duct **164** is lowered accordingly. Thus, a reduction in thickness of the duct **164** and a reduction in weight due to the reduction in thickness can be realized.

If $\theta 1, \theta 2$ are below the above lower limit value and the distance **L** between the first and second axes **J1**, **J2** is short, the duct **164** has a large curvature and processing to increase the strength of the duct **164**, for example, increasing the thickness of the duct **164** or the like may be necessary. On the contrary, if $\theta 1, \theta 2$ exceed the above upper limit value, the wires **170** in the curved portions **162c**, **163c** of the first and second joints **162**, **163** have a small curvature and processing to increase the strength of the wires **170**, for example, increasing the thickness of a coating layer or the like may be necessary.

In this embodiment, the duct connecting portions **162b**, **163b** of the first and second joints **162**, **163** are arranged at the same height. In other words, the duct connecting portions

162b, **163b** are provided within the same plane as the normals of the first and second axes **J1**, **J2**. Moreover, the duct connecting portions **162b**, **163b** have the same slope ($\theta 1, \theta 2$), as described above. Therefore, the curvature of the duct **164** can be made substantially constant along the axial direction and the concentration of bending stress on a predetermined part of the duct **164** can be prevented or restrained. Since the part where stress concentrates tends to be the starting point of vibration, by preventing or restraining the concentration of stress, vibration of the duct **164** at the time when the first and second arms **120**, **130** are driven or stopped can be prevented or restrained more effectively. Also, since the strength required of the duct **164** is lowered, a reduction in thickness of the duct **164** and a reduction weight due to the reduction in thickness can be realized.

It is preferable that the duct **164** (portions excluding the parts overlapping with the first and second joints **162**, **163**) extends so that the center axis thereof is along a circle (circumference) having the center axis **J3** of the duct connecting portion **162b** and the center axis **J4** of the duct connecting portion **163b** as tangents. In such a curved state, an equal bending stress is applied to substantially the entire area of the duct **164** and therefore local concentration of stress on a predetermined part of the duct **164** can be prevented more securely. Therefore, vibration of the duct **164** at the time when the first and second arms **120**, **130** are driven or stopped can be prevented or restrained more securely.

Particularly, in this embodiment, since the first and second joints **162**, **163** have the same shape and size, the duct connecting portions **162b**, **163b** can be easily arranged at the same height, for example, by equalizing the installation height of the first and second joints **162**, **163**. Since the first and second joints **162**, **163** thus have the same shape and size, components can be made interchangeable. Thus, the manufacturing cost of the horizontal multi-joint robot **100** can be restrained and the horizontal multi-joint robot **100** can be designed easily.

The above is the description of the horizontal multi-joint robot **100**.

While the duct **164** is flexible in this embodiment, the duct **164** may be rigid. As described above, the duct **164** does not substantially deform no matter how the first and second arms **120**, **130** are driven. Therefore, even if the duct **164** is rigid, this does not affect the driving of the horizontal multi-joint robot **100**. If the duct **164** is made of a rigid material, it is preferable that the duct **164** is made of, for example, a metallic material with environmental resistance. Thus, the horizontal multi-joint robot **100** suitable for use in a special environment is provided.

Robot

Next, a robot will be described.

FIG. 3 is a perspective view showing a preferred embodiment of a robot. FIG. 4 is a view showing a first wiring section provided in the robot shown in FIG. 3. FIG. 5 is a view showing a second wiring section provided in the robot shown in FIG. 3.

A robot **300** shown in FIG. 3 is a vertical multi-joint (six-axis) robot having a pedestal **310**, four arms **320**, **330**, **340**, **350**, and a wrist **360** that are connected in order.

The pedestal **310** is fixed, for example, to a floor surface which is not shown in the drawing with bolts or the like. The arm **320** with an attitude inclined in relation to horizontal direction is connected to an upper end of such a pedestal **310**. The arm **320** is capable of swiveling around an axis **J6** that extends along a vertical direction in relation to the pedestal **310**.

Inside the pedestal **310**, a first motor **311** which causes the arm **320** to swivel, and a first decelerator **312** are installed. Although not shown, an input axis of the first decelerator **312** is connected to a rotation axis of the first motor **311**, and an output axis of the first decelerator **312** is connected to the arm **320**. Therefore, when the first motor **311** is driven and a driving force thereof is transmitted to the arm **320** via the first decelerator **312**, the arm **320** swivels within a horizontal plane around the axis J6 in relation to the pedestal **310**. The first motor **311** is provided with a first encoder **313** which outputs a pulse signal corresponding to the amount of rotation of the first motor **311**. Based on the pulse signal from the first encoder **313**, the amount of swiveling of the arm **320** in relation to the pedestal **310** can be detected.

The arm **330** is connected to a distal end of the arm **320**. The arm **330** is capable of swiveling around an axis J7 that extends along a horizontal direction in relation to the arm **320**.

Inside the arm **330**, a second motor **331** which causes the arm **330** to swivel in relation to the arm **320**, and a second decelerator **332** are installed. Although not shown, an input axis of the second decelerator **332** is connected to a rotation axis of the second motor **331**, and an output axis of the second decelerator **332** is connected and fixed to the arm **320**. Therefore, when the second motor **331** is driven and a driving force thereof is transmitted to the arm **320** via the second decelerator **332**, the arm **330** swivels within a horizontal plane around the axis J7 in relation to the arm **320**. The second motor **331** is provided with a second encoder **333** which outputs a pulse signal corresponding to the amount of rotation of the second motor **331**. Based on the pulse signal from the second encoder **333**, the driving (amount of swiveling) of the arm **330** in relation to the arm **320** can be detected.

The arm **340** is connected to a distal end of the arm **330**. The arm **340** is capable of swiveling around an axis J8 that extends along a horizontal direction in relation to the arm **330**.

Inside the arm **340**, a third motor **341** which causes the arm **340** to swivel in relation to the arm **330**, and a third decelerator **342** are installed. Although not shown, an input axis of the third decelerator **342** is connected to a rotation axis of the third motor **341**, and an output axis of the third decelerator **342** is connected and fixed to the arm **330**. Therefore, when the third motor **341** is driven and a driving force thereof is transmitted to the arm **330** via the third decelerator **342**, the arm **340** swivels within a horizontal plane around the axis J8 in relation to the arm **330**. The third motor **341** is provided with a third encoder **343** which outputs a pulse signal corresponding to the amount of rotation of the third motor **341**. Based on the pulse signal from the third encoder **343**, the driving (amount of swiveling) of the arm **340** in relation to the arm **330** can be detected.

The arm **350** is connected to a distal end of the arm **340**. The arm **350** is capable of swiveling around an axis J9 that extends along a center axis of the arm **340** in relation to the arm **340**.

Inside the arm **350**, a fourth motor **351** which causes the arm **350** to swivel in relation to the arm **340**, and a fourth decelerator **352** are installed. An input axis of the fourth decelerator **352** is connected to a rotation axis of the fourth motor **351**, and an output axis of the fourth decelerator **352** is connected and fixed to the arm **340**. Therefore, when the fourth motor **351** is driven and a driving force thereof is transmitted to the arm **340** via the fourth decelerator **352**, the arm **350** swivels within a horizontal plane around the axis J9 in relation to the arm **340**. The fourth motor **351** is provided with a fourth encoder **353** which outputs a pulse signal corresponding to the amount of rotation of the fourth motor **351**.

Based on the pulse signal from the fourth encoder **353**, the driving (amount of swiveling) of the arm **350** in relation to the arm **340** can be detected.

The wrist **360** is connected to a distal end of the arm **350**. The wrist **360** has a ring-shaped support ring connected to the arm **350**, and a cylindrical wrist main body supported on a distal end of the support ring. A distal end surface of the wrist main body is a flat surface and serves, for example, as a mounting surface where a manipulator holding a precision device such as a wristwatch is mounted.

The support ring is capable of swiveling around an axis J10 that extends along a horizontal direction in relation to the arm **350**. The wrist main body is capable of swiveling around an axis J11 that extends along a center axis of the wrist main body in relation to the support ring.

Inside the arm **350**, a fifth motor **354** which causes the support ring to swivel in relation to the arm **350**, and a sixth motor **355** which causes the wrist main body to swivel in relation to the support ring are arranged. Driving forces of the fifth and sixth motors **354**, **355** are transmitted to the support ring and the wrist main body, respectively, by a driving force transmission mechanism, not shown. The fifth motor **354** is provided with a fifth encoder **356** which outputs a pulse signal corresponding to the amount of rotation of the fifth motor **354**. Based on the pulse signal from the fifth encoder **356**, the amount of swiveling of the support ring in relation to the arm **350** can be detected. Also, the sixth motor **355** is provided with a sixth encoder **357** which outputs a pulse signal corresponding to the amount of rotation of the sixth motor **355**. Based on the pulse signal from the sixth encoder **357**, the amount of swiveling of the wrist main body in relation to the support ring can be detected.

Plural wires **370** connected to individual electronic components (for example, third, fourth, fifth and sixth motors **341**, **351**, **354**, **355**, third, fourth, fifth and sixth encoders **343**, **353**, **356**, **357** and the like) arranged inside the arms **340**, **350** pass through a pipe-like first wiring section **380** connecting the arm **340** and the arm **330** to each other and are drawn into the arm **340**. Also, the plural wires **370** pass through a pipe-like second wiring section **390** connecting the arm **330** and the arm **320** to each other and are drawn into the arm **320**. Moreover, the plural wires **370** are bundled inside the arm **320** and thus drawn to the pedestal **310** together with wires connected to the second motor **331** and the second encoder **333**. The wires are then bundled inside the pedestal **310** and thus drawn up to a control device, not shown, which is installed outside the pedestal **310** and generally controls the robot **300**, along with the wires connected to the first motor **311** and the first encoder **313**.

Since the wires **370** of the individual electronic components inside the arms **340**, **350** are thus drawn into the pedestal **310** via the first and second wiring sections **380**, **390**, a large space for drawing the wires **370** need not be secured within the arms **320**, **330**. Therefore, as in the foregoing horizontal multi-joint robot **100**, a reduction in the size and weight of the robot **300** can be realized.

As shown in FIG. 4, the first wiring section **380** has a first joint **382**, a second joint **383**, and a duct **384**. These components are connected in order of the first joint **382**, the duct **384**, and the second joint **383**, from the side of the arm **330**. A wire insertion hole (not shown) which connects the insides of the arm **330** and the arm **340** to each other is formed within the first wiring section **380**. That is, the first joint **382**, the second joint **383**, and the duct **384** are all pipe-shaped and have open inner spaces thereof connected in series.

The first joint **382** is received by a bearing on the arm **330** and is capable of swiveling around an axis J12 in relation to

11

the arm 330. Meanwhile, the second joint 383 is received by a bearing on the arm 340 and is capable of swiveling around the axis J8 in relation to the arm 340. The axis J12 is parallel to the axis J8. Therefore, no matter how the arm 340 is driven in relation to the arm 330, a distance between the axes of the first and second joints 382, 383 is kept constant. Therefore, deformation (expansion or contraction) of the duct 384 connected at both ends to the first and second joints 382, 383 is prevented or restrained. Consequently, vibration of the duct 384 at the time when the arm 340 is driven or when the driving is stopped can be prevented or restrained.

The first joint 382, the second joint 383 and the duct 384 have similar configurations to the first joint 162, the second joint 163 and the duct 164 of the foregoing horizontal multi-joint robot 100, respectively, and therefore will not be described further in detail. Also, with respect to the first wiring section 380, the arm 330, the arm 340, the axis J12 and the axis J8 are equivalent to the first arm, the second arm, the first axis and the second axis described in the appended claims, respectively.

As shown in FIG. 5, the second wiring section 390 has a first joint 392, a second joint 393, and a duct 394. These components are connected in order of the first joint 392, the duct 394, and the second joint 393, from the side of the arm 320. A wire insertion hole (not shown) which connects the insides of the arm 320 and the arm 330 to each other is formed within the second wiring section 390. That is, the first joint 392, the second joint 393, and the duct 394 are all pipe-shaped and have open inner spaces thereof connected in series.

The first joint 392 is received by a bearing on the arm 320 and is capable of swiveling around an axis J13 in relation to the arm 320. Meanwhile, the second joint 393 is received by a bearing on the arm 330 and is capable of swiveling around the axis J7 in relation to the arm 330. The axis J13 is parallel to the axis J7. Therefore, no matter how the arm 330 is driven in relation to the arm 320, a distance between the axes of the first and second joints 392, 393 is kept constant. Therefore, deformation (expansion or contraction) of the duct 394 connected at both ends to the first and second joints 392, 393 is prevented or restrained. Consequently, vibration of the duct 394 at the time when the arm 330 is driven or when the driving is stopped can be prevented or restrained.

The first joint 392, the second joint 393 and the duct 394 have similar configurations to the first joint 382, the second joint 383 and the duct 384, respectively, and therefore will not be described further in detail. Also, with respect to the second wiring section 390, the arm 320, the arm 330, the axis J13 and the axis J7 are equivalent to the first arm, the second arm, the first axis and the second axis described in the appended claims, respectively.

The above is the description of the robot 300.

A horizontal multi-joint robot and a robot are described above, based on the illustrated embodiments. However, the invention is not limited to these embodiments and the configuration of each part can be replaced by an arbitrary configuration having similar functions. Also, other arbitrary components may be added within the scope of the invention.

The entire disclosure of Japanese Patent Application No. 2012-233499 filed Oct. 23, 2012 is hereby expressly incorporated by reference herein.

What is claimed is:

1. A horizontal multi-joint robot comprising:

a first joint that is rotatable around a first axis;

a second joint that is rotatable around a second axis, the second axis being parallel to and spaced apart from the first axis; and

12

a duct connected between the first joint and the second joint;

wherein the first joint has a first connecting portion positioned at a first incline relative to the first axis,

the second joint has a second connecting portion positioned at a second incline relative to the second axis, and the duct has a first end and a second end, the first end being connected to the first connecting portion, and the second end being connected to the second connecting portion.

2. The horizontal multi-joint robot according to claim 1, wherein a duct connecting portion of the first joint and a duct connecting portion of the second joint are provided within the same plane as normals of the first axis and the second axis.

3. The horizontal multi-joint robot according to claim 1, wherein an angle formed by the first axis and a center axis of the first connecting portion is equal to an angle formed by the second axis and a center axis of the second connecting portion.

4. The horizontal multi-joint robot according to claim 1, wherein an angle formed by the first axis and a center axis of the first connecting portion is 10° or more and 60° or less, and an angle formed by the second axis and a center axis of the second connecting portion is 10° or more and 60° or less.

5. The horizontal multi-joint robot according to claim 1, wherein the first joint and the second joint have the same shape and size.

6. The horizontal multi-joint robot according to claim 1, wherein the duct extends along a circle having both a center axis of the first connecting portion and a center axis of the second connecting portion as tangents.

7. The horizontal multi-joint robot according to claim 1, wherein an average radius of curvature of the duct is equal to or short than a distance between the first axis and the second axis, and the average radius is equal to or long than a length 0.6 times the distance.

8. The horizontal multi-joint robot according to claim 1, wherein a distance between the first axis and the second axis is 100 mm or more and 2000 mm or less.

9. A robot comprising:

a pedestal;

a first arm connected to the pedestal and being rotatable around a first axis relative to the pedestal;

a second arm connected to the first arm and being rotatable around a second axis that is parallel to and spaced apart from the first axis; and

a wiring section which accommodates a wire therein, the wire extending from the second arm to the pedestal,

wherein the wiring section includes:

a duct supporting portion that protrudes from the pedestal and intersects the first axis;

a first joint connected to the duct supporting portion and being rotatable around the first axis relative to the duct supporting portion;

a second joint connected to the second arm and being rotatable around the second axis relative to the second arm; and

a duct connected between the first joint and the second joint,

wherein the first joint has a first connecting portion located at a first incline relative to the first axis,

the second joint has a second connecting portion located at a second incline relative to the second axis, and

the duct has a first end and a second end, the first end being connected to the first connecting portion, and the second end being connected to the second connecting portion.

10. A robot comprising:

a pedestal;

13

14

a first arm rotatably connected to the pedestal about a first axis;
 a second arm rotatably connected to the first arm about a second axis parallel to and spaced apart from the first axis; and
 a wiring section accommodating a wire therein that extends from the second arm to the pedestal,
 wherein the wiring section includes:
 a duct supporting portion protruding from the pedestal;
 a first joint connected to the duct supporting portion and being rotatable around the first axis relative to the duct supporting portion;
 a second joint connected to the second arm and being rotatable around the second axis relative to the second arm; and
 a duct connected between the first joint and the second joint,
 wherein the first joint has a first connecting portion inclined relative to the first axis,
 the second joint has a second connecting portion inclined relative to the second axis, and
 the duct has a first end connected to the first connecting portion, and a second end connected to the second connecting portion.

11. The robot according to claim **10**, wherein the first and second connecting portions are inclined at equal angles.

12. The robot according to claim **10**, wherein an upper surface of the duct supporting section is substantially coplanar with an upper surface of the second arm.

13. The robot according to claim **10**, wherein the duct curves along a circular arc between the first and second connecting portions.
